Abstract

This paper presents a new sensorless direct torque control method for voltage inverter – fed PMSM. The control method is used a modified Direct Torque Control scheme with constant inverter switching frequency using Space Vector Modulation (DTC-SVM). The variation of stator and rotor resistance due to changes in temperature or frequency deteriorates the performance of DTC-SVM controller by introducing errors in the estimated flux linkage and the electromagnetic torque. As a result, this approach will not be suitable for high power drives such as those used in tractions, as they require good torque control performance at considerably lower frequency. A novel stator resistance estimator is proposed. The estimation method is implemented using the Extended Kalman Filter. Finally extensive simulation results are presented to validate the proposed technique. The system is tested at different speeds and a very satisfactory performance has been achieved.

Keywords: DTC, SVM, (PMSM), Extended Kalman Filter (EKF), Sensorless.

1. Introduction

Permanent magnet (PM) synchronous motors are widely used in high-performance drives such as industrial robots and machine tools. These motors have many advantages as: high efficiency and power density, high-torque/inertia ratio. The fast development of power-and microelectronics and computer science opened a new way of investigation for PMSM with vector control strategies [1, 2]. Firstly DTC was proposed for IM [3], however now is applied also for PMSM [4]. Direct Torque Control (DTC) seems to be a good performance alternative to the classical vector control drives. After its implementation on induction motor drives, this control method in recent years has been proposed for permanent magnet synchronous motor with good results. DTC is able to produce fast torque and stator flux response with a well designed flux, torque and speed estimator. In order to reduce the torque and current pulsations, in steady state a mixed DTC- SVM control method seems more suitable.

SVM techniques [5, 6] offer better DC link utilization and they lower the torque ripple. The emphasis of research on PMSM has been on sensorless drive [7, 8, 9, 10], which eliminates flux and speed sensors mounted on the motor. In addition, the development of effective speed and flux estimators has allowed good rotor flux-oriented performance at all speeds except those close to zero. Sensorless control has improved the motor performance, compared to the Volts/Hertz (or constant flux) controls.

The EKF is considered to be suitable for use in high-performance PMSM drives, and it can provide accurate speed estimates in a wide speed-range, including very low speed [11, 12].

The variation of stator resistance due to changes in temperature or frequency deteriorates the performance of DTC controller by introducing errors in the estimated flux linkage and the electromagnetic torque [13, 14, 15, 16]. A novel stator resistance estimator during the operation of the motor is proposed.

This paper describes a novel DTC-SVM method for a speed sensorless control of PMSM drive. According to this method, a conventional PI predictive controller is used to determine the polar components of the voltage command vector. The results show that a satisfactory control performance is obtained.

2. Modeling of the PMSM

The electrical and mechanical equations of the PMSM in the rotor reference (d,q) frame as follows:

\[
\begin{align*}
\frac{dI_d}{dt} &= \frac{R_d}{L_d} I_d + \frac{1}{L_d} U_d \\
\frac{dI_q}{dt} &= \frac{R_d}{L_q} I_q + \frac{1}{L_q} U_q + \frac{P_0}{L_q} \left( \frac{\Phi_r}{L_q} I_d + \frac{\Phi_r}{L_q} I_q \right) T_L - \frac{B}{J} \omega_r \\
\frac{d\omega_r}{dt} &= \frac{3P}{2J} \left[ (L_d - L_q) I_q I_d (L_q I_d + \Phi_r I_q) - I_d \right] T_L - \frac{B}{J} \omega_r
\end{align*}
\]
where $I_d$, $I_q$ are the $d$-$q$ axis currents, $U_d$, $U_q$ are the $d$-$q$ axis voltages, $\omega_r$ denotes the rotor speed, $R_s$ is the stator resistance, $L_d$, $L_q$ are the stator inductances, $P$ is the pole pairs, $J$ is the rotor moment of inertia, $B$ is the viscous friction coefficient, $T_L$ is the load torque.

The block scheme of the investigated direct torque control with space vector modulation (DTC-SVM) for a voltage source PWM inverter fed PMSM is presented in Figure 1(a).

The internal structure of the predictive torque and flux controller is shown in Figure 1(b).

The objective of the DTC-SVM scheme, and the main difference between the classic DTC, is to estimate a reference stator voltage vector $V_{s \text{ ref}}$ in order to drive the power gates of the inverter with a constant switching frequency. Although, the basic principle of the DTC is that the electromagnetic torque of the motor can be adjusted by controlling the angle $\Delta \delta$ between the stator and rotor flux vectors, the torque of a PMSM can be calculated by the following equation.

\[
\Delta T_L = 3 \left( \frac{p}{2} \right) \left[ \frac{1}{L_d} \right] \sin \Delta \delta
\]

(3)

Where the change in the stator flux vector, if we neglect the voltage drop in the stator resistance, can be given by the following equation,

\[
\Delta \Phi_s = V_s T_s
\]

(4)

Where $\Delta \Phi_s$ is the deviation from $|\Phi_s|$ which are defined by:

\[
\Delta \Phi_s = |\Phi_{s \text{ ref}}| - |\Phi_s|
\]

(5)

The predictive controller determines the stator voltage command vector in polar coordinates $V_{s \text{ ref}}[V_{s \text{ ref}}, \delta]$ for space vector modulator, which finally generates the pulses $S_a$, $S_b$, $S_c$.

Sampled torque error $\Delta T_e$ and reference stator flux amplitude $\Phi_{s \text{ ref}}$ are delivered to the predictive controller. The relation between error of torque and increment of load and angle $\Delta \delta$ is nonlinear. Therefore PI controller, which generates the load angle increment required to minimize the instantaneous error between reference $T_{\text{ref}}$ and actual $T_e$ torque, has been applied. The reference values of the stator voltage $V_{s \text{ ref}}$, $\gamma_{s \text{ ref}}$ is calculated based on stator resistance $R_s$, $\Delta \delta$ signal, actual stator current vector $I_s$, actual stator flux amplitude $\Phi_s$ and position $\gamma_s$ as: The $\alpha$, $\beta$ axes components of the stator reference voltage $V_{s \text{ ref}}$, are calculated according to the following equation:

\[
V_{sa \text{ ref}} = \frac{\Phi_{s \text{ ref}} \cos(\gamma_s + \Delta \delta) \cdot \Phi_{s \text{ ref}} \cos(\gamma_s)}{T_s} + \hat{R}_s I_{sa}
\]

(6)

\[
V_{sb \text{ ref}} = \frac{\Phi_{s \text{ ref}} \sin(\gamma_s + \Delta \delta) \cdot \Phi_{s \text{ ref}} \sin(\gamma_s)}{T_s} + \hat{R}_s I_{sb}
\]

(7)
\[ V_{s,ref} = \sqrt{V_{s\alpha,ref}^2 + V_{s\beta,ref}^2} \]  

\[ \gamma_{s,ref} = \arctan \left( \frac{V_{s\beta,ref}}{V_{s\alpha,ref}} \right) \]  

Where, \( T_s \) is sampling time.

### 3. Voltage Space Vector Modulation

The voltage vectors, produced by a 3-phase PWM inverter, divide the space vector plane into six sectors as shown in Figure 3.

In every sector, each voltage vector is synthesized by basic space voltage vector of the two side of sector and one zero vector. For example, in the first sector, \( V_{s,ref} \) is a synthesized voltage space vector and expressed by:

\[ V_{s,ref} = V_s T_0 + V_1 T_1 + V_2 T_2 \]  

Where \( T_0, T_1 \) and \( T_2 \) is the work time of basic space voltage vectors \( V_0, V_1 \) and \( V_2 \) respectively.

The determination of the amount of times \( T_1 \) and \( T_2 \) is given by simple projections:

\[ T_1 = \frac{T_s}{2E} \left( \sqrt{6} V_{s\beta,ref} - \sqrt{2} V_{s\alpha,ref} \right) \]  

\[ T_2 = \sqrt{2} \frac{T_s}{E} V_{s\beta,ref} \]  

The rest of the period spent in applying the null-vector. For every sector, commutation duration is calculated. The amount of times of vector application can all be related to the following variables:

\[ X = \frac{T_s}{E} \sqrt{2} V_{s\beta,ref} \]  

\[ Y = \frac{T_s}{E} \left( \frac{\sqrt{2}}{2} V_{s\beta,ref} - \frac{\sqrt{6}}{2} V_{s\alpha,ref} \right) \]  

\[ Z = \frac{T_s}{E} \left( -\frac{\sqrt{2}}{2} V_{s\beta,ref} - \frac{\sqrt{6}}{2} V_{s\alpha,ref} \right) \]  

The application durations of the sector boundary vectors are tabulated as follows:

**Table 1. Durations of the sector boundary vectors.**

<table>

The goal of this step is to compute the three necessary duty cycles as:

\[ T_{non} = \frac{T_s}{2} \left( T_1 - T_2 \right) \]  

\[ T_{bias} = T_{non} + T_1 \]  

\[ T_{con} = T_{bias} + T_2 \]  

The last step is to assign the right duty cycle \( T_{non} \) to the right motor phase according to the sector.

4. Extended Mathematical Model of the PMSM

In this study, EKF, is used for the estimation of \( I_d \), \( I_q \), \( \omega_r \), \( \delta \), T, and \( \bar{R}_s \).

Figure 5 shows the structure of a Kalman filter

\[
\begin{align*}
A_d &= \begin{bmatrix}
    (1-a_1R_s(k)) & a_5\omega_0(k) & 0 & 0 & 0 & a_1 \\
    -a_4\omega_0(k) & (1-a_1R_s(k)) & -a_6 & 0 & 0 & a_3 \\
    a_4I_d(k) & a_9 & 1-a_{10} & 0 & a_{11} & 0 \\
    0 & 0 & 0 & a_{12} & 1 & 0 \\
    0 & 0 & 0 & 0 & 0 & 1 \\
    0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix} \\
B_d &= \begin{bmatrix}
a_3 \\
0 \\
a_7 \\
0 \\
0 \\
0
\end{bmatrix}
\end{align*}
\]

Where:

\[
f(x(k), u(k)) = \begin{bmatrix}
f_1 \\
f_2 \\
f_3 \\
f_4 \\
f_5 \\
f_6
\end{bmatrix}
\]

5. Application of the Extended Kalman Filter

The speed estimation algorithm of the extended Kalman filter can be simulated by the MATLAB/Simulink software, which consists of an S-Function block as shown in Figure 5.
5.1. Prediction of the State Vector
Prediction of the state vector at sampling time \( k+1 \), from the input \( u(k) \), state vector at previous sampling time \( x(k/k) \).

\[
\hat{x}(k+1/k) \triangleq f(\hat{x}(k/k), u(k)) \tag{24}
\]

5.2. Prediction Covariance Computation
The prediction covariance is updated by:

\[
P(k+1/k) = f(k)P(k)f(k)^T + Q \tag{25}
\]

Where: Q: covariance matrix of the system noise,

\[
F(k) = \frac{\partial f}{\partial x}\bigg|_{x(k)=\hat{x}(k/k)} \tag{26}
\]

5.3. Kalman Gain Computation
The Kalman filter gain (correction matrix) is computed as;

\[
L(k+1) = P(k+1/k)C(k)^T (C(k)P(k+1/k)C(k)^T + R)^{-1} \tag{27}
\]

With:

\[
C(k) = \frac{\partial c(x(k))}{\partial x(k)}\bigg|_{x(k)=\hat{x}(k/k)} \tag{27}
\]

5.4. State Vector Estimation
The predicted state-vector is added to the innovation term multiplied by Kalman gain to compute state-estimation vector. The state-vector estimation (filtering) at time \( k \) is determined as:

\[
\hat{x}(k+1/k+1) = \hat{x}(k+1/k) + L(k+1)\gamma(k+1) - CS(\hat{x}(k+1/k)) \tag{28}
\]

6. Proposed Sensorless PMSM Drive
The proposed sensorless PMSM drive is depicted in Figure 6. The stator flux is estimated by the EKF and used in the DTC control.

7. Simulation Results
In this section, the effectiveness of the proposed algorithm is verified by computer simulations. During the simulations, the torque set value is limited to 5 N.m (rated torque). In order to show the performances and the robustness of the combined DTC-SVM-EKF algorithm, a series of tests were conducted to check the performance of the proposed DTC-SVM. In all sketched figures, the time axis is scaled in seconds. The block scheme of the investigated direct torque control with space vector modulation (DTC-SVM) for a voltage source inverter fed PMSM is presented in (Figure 6).

The specifications for the used PMSM are listed in Table 3.

Figure 7 shows the actual and estimated responses of the proposed sensorless scheme. The machine is started from rest and assumed to follow a certain speed trajectory. A load torque of 5 N.m is assumed to be applied at time 0.15s. Current ripple has also a notable reduction in DTC-SVM compared to classic DTC. DTC-SVM has a significantly lower ripple level both in torque, flux and stator current, a lower current ripple advantageous because the machine will have less EMI noise.

Figure 8 show the trajectory of the estimated stator flux components DTC-SVM has as good dynamic response as the classical DTC.
Figure 7. Simulation results: A load torque of 5 N.m is applied at t = 0.15 sec.
In this paper an extended Kalman filter (EKF) algorithm is developed for the speed sensorless direct torque control strategy combined with space vector modulation. The complete sensorless solution is presented with the combined DTC-SVM-EKF strategy; low torque ripple operation has been obtained with PMSM. In spite of lower switching frequency, the DTC-SVM scheme has lower harmonic current, and consequently lower ripple than conventional hysteresis based DTC. Simulation results obtained clearly demonstrate the effectiveness of the estimator in estimating the stator resistance and improving performance of DTC. Additionally, the application of SVM guarantee:

- Inverter switching frequency is constant;
- Distortion caused by sector changes is delimited;
- Low sampling frequency is required;
- High robustness;
- Good dynamic response;
- Low complexity.

8. Conclusion
